(December 2020) (LEARN as and when removing this template message) The ISO screw thread is the most commonly used type of generic screw thread around the world. [1] They were one of the first international standards agreed when the international standardization organization (ISO) was established in 1947. Designation "m" for metric screws indicates the nominal outer diameter of the screw wire, in millimeters. This is also indicated as the "major" diameter in the information below. Indicates the diameter of the smooth wall hole that a male wire (for example on a bolt) will pass easily to create a well-positioned connection to a threaded component internally (for example a dice) on the other side. That, a screw M6 has a nominal outer diameter of 6 millimeters and will therefore be a well-positioned shape, coaxial in a 6 mm diameter perforated hole. Basic profile of all ISO metric screw fillets, where the male part has the external wire the design principles of metric screw threads for general purposes ISO ("M" series threads) are defined in the international ISO 68-1 standard. [2] Each fillet is characterized by its larger diameter, D (DMAJ in the diagram), and its field, the metric wires P. ISO consist of a symmetrical wire in the shape of V. in the plane of the thread axis, The sides of the V have an angle of 60 ° to one another. The profinity of the thread is 0.54125 ia-pitch. The external 1Â "8 and the finest 1Â" 4 of the V-Shape height are cut off the profile. The ratio between H height and the P field is using the following equation where Î¸ is metÃÃ¨ the included angle of the thread, in this case 30Â °: [3] h = 1 2 tan Â ¡Î¸ Â Ž p = 3 2 ÂŽ Â ‰ 0.866025 âž â {displaystyle translation:)}} cdot p = {frac {sqrt {3}} {2}} cdot p approx 0.866025 cdot p} or p = 2 tan â ¡Î¸ ÂŽ Â 3 Â 3 ÂŽ Â ‰ 1,154701 ï ‡ h {DisplayStyle p = 2 TANTA CDOT H = {Frac { 2} {sqrt {3} cdot h approx 1.15 H. In an external wire (male) (for example, on a bolt), the Major DMAJ diameter and the minor diameter DMIN define the maximum dimensions of the wire. This means that the external wire must end up dish to Dmaj, but can be rounded under the minor diameter DMIN. In reverse, an internal wire (female) (for example, in a nut), the main and minor diameters are minimal minimum then the thread profile must end flat at Dmin but can be rounded over Dmaj. In practice this means that you can measure the diameter above the threads of a bolt to find the nominal diameter Dmaj, while the inner diameter of a nut is Dmin. > > >
