Greenhouse effect seminar pdf

The Earth has a natural greenhouse effect due to water vapour traces (H2O), carbon dioxide (CO2), methane (CH4) and nitrous oxide (N2O) in the atmosphere. These gases allow solar radiation to reach the surface of the Earth, but absorb infrared radiation emitted by the Earth and thus lead to the heating of the surface of the planet. You should distinguish between the natural greenhouse effect and the enhanced greenhouse effect. The natural greenhouse effect is caused by the natural amounts of greenhouse gases, and is vital for life. In the absence of the natural greenhouse effect the surface of the Earth would be about 33 degrees Celsius cooler. The enhanced greenhouse effect refers to the additional radiative forcing resulting from higher concentrations of greenhouse gases induced by human activities. The main greenhouse gases whose concentrations are carbon dioxide, methane, nitrous oxide, chlorofluorocarbons (HCFC), hydrocarbons (HFC) and ozone in the lower atmosphere. The Global Atmosphere Watch (GAW) looks, analyzes, and publishes the data of greenhouse gases collected from fifty countries around the world from the High Arctic to the South Pole. Monitored greenhouse gases include: carbon dioxide (CO2) (incl. Δ14C, δ13C and δ18O in CO2, and O2/N2 Ratios) methane (CH4) Nitrose oxide (N2O) Halocarbons and SF6 Molecular Hydrogen (H2) The data is collected and distributed by the World Data Centre for Greenhouse Gases (WDCGG)Japan Meteorological Agency. The GAW scientific advisory group for greenhouse gases (SAG-GHG) recommends the development of the program. GAW publishes the annual Bulletin of greenhouse gases, which shows the latest trends and atmospheric burdens of the most influential greenhouse gases, long-term, carbon dioxide (CO2), methane (CH4), and nitrose oxide (N2O), as well as a summary of lower gas contributions. Updated on April 23, 2018 By Milton Kazmeyer One of the factors affecting the environmental conditions of the world is the greenhouse effect. Climate scientists often blame the greenhouse effect to contribute to Earth's environmental customs, but also have a positive vital effect on the planet. Without this atmospheric condition, life on Earth would be very different, or even non-existent. The greenhouse effect refers to the ability of the atmosphere to trap the heat of the sun, increasing the temperature of the planet. When the energy of the sun reaches Earth, the atmosphere absorbs some along the way downwards, and then absorbs more when that energy is reflected back from the surface during the day. This trapped energy warms the atmosphere, increasing the temperature of the planet and distributing heat to its night side, when solar heating is not available. The densest the atmosphere, and the higher the concentration of energy-holding molecules as water vapor and carbon dioxide, the more energy the atmosphere can trap. The greenhouse effect is important, because to the survival of life on Earth. Without the greenhouse effect, the temperature of the planet would be similar to the conditions experienced on the moon. On the lunar surface, without atmosphere to mediate temperature fluctuations, the surface can reach 134 degrees Celsius (273 degrees Fahrenheit) during the day and -153 degrees Celsius (-244 degrees Fahrenheit) at night. This dramatic temperature change required NASA to develop specialized tools to protect astronauts from both extremes for lunar landings. A similar obsession of temperature on Earth would produce a hostile environment to most living things. Unfortunately, while a moderate greenhouse effect is vital to life, a high greenhouse effect can be dangerous. Since the Industrial Revolution, the widespread adoption of fossil fuels has increased the amount of carbon dioxide, water vapor and other greenhouse gases in the atmosphere. According to a study of the Carbon Dioxide Information Analysis Center of the U.S. Department of Energy, carbon dioxide levels increased by 39.5 percent from 1750, while methane levels in the atmosphere fell by 150 percent. Climate scientists point to this increase in thermotraction gases as one of the reasons why global temperatures have increased during this period. One of the main concerns about an increase in greenhouse effect is that changes can become self-susing. While more greenhouse gases enter the atmosphere, its ability to trap heat increases. Like heat the atmosphere increases, the amount of water vapor that can keep increases as well, further increasing the effect. In addition, the increase in global temperatures threatens to release large amounts of carbon that is currently frozen in permafrost areas, even aggravating the problem. Excessive heat retention could lead to huge changes in natural water distribution and land mass available globally. The effect of mitigating factors, such as cloud cover increased by reflecting sunlight again in space, is not well understood.
