How to search latitude and longitude on apple maps

As one of the most powerful mapping tools available, Google Maps has a number of features designed to help you pinpoint your location. If you want to know your exact position, you can pull up your GPS coordinates in Google Maps. You can get coordinates on all platforms, including the Google Maps website, as well as the Google Maps app for Android, iPhone, and iPad. Use the Google Maps Website to Find Coordinates You can easily find the GPS coordinates (showing the latitude and longitude) for a location using the Google Maps website. These steps work for Maps in any web browser, not just Google Chrome. To do this, search for a location in the search bar at the top of the Google Maps website, or use your mouse to zoom in on a location on the visible map. Once you've nailed down a location, right-click it to bring up an additional options menu. From the pop-up menu, select the "What's Here?" option. The button will bring up a small location box at the bottom of the page. You'll see a series of numbers under the location. These are your GPS coordinates, shown as decimal degrees. If you wanted to search for this location in Google Maps again, you could search for these coordinates in the search bar. Google Maps would then display the location for you to find more information about, or to help you create a custom map showing directions and other areas of interest around it. RELATED: How to Create a Custom Map in Google Maps Use the Google Maps Mobile App to Find Coordinates You can also use the Google Maps mobile app for Android, iPhone, and iPad to locate the exact GPS coordinates for any location worldwide. The steps for Android and Apple users are similar, but the iPhone and iPad have an additional step to follow. To find GPS coordinates, open the Google Maps app on your smartphone or tablet. You can use the search bar to find a general location or use the map view to locate it manually. If you're using the map view, you'll need to long-touch and select an unmarked location until a red pin appears. The coordinates will be displayed in the Google Maps for Android search bar when you drop a pin. You'll need to tap the "Dropped Pin" box at the bottom of the Google Maps app for iPhone and iPad. This screen appears after you've dropped a red pin onto the map view. Tapping "Dropped Pin" will bring up an information menu with the location address, as well as options to save or find directions to the location. The coordinates for the location will be listed under the address at the bottom of the menu. RELATED: How to View and Delete Your Google Maps History on Android and iPhone Both Apple Maps and Google Maps are popular options when it comes to knowing you've got a comprehensive navigational tool on your smartphone. At first, Apple Maps had a few navigational issues but they're both pretty top-notch now and offer great services entirely for free. So, you really can't go wrong with either option. However, both services do offer some important differences. Apple Maps is only available for Apple devices including iPhones, iPads, Apple Watch, and Mac systems. Google Maps is available for all those devices, as well as Android smartphones and tablets, and it's also available through its website. Lifewire The battle of Apple vs Google Maps used to be a fairly easy fight when Apple Maps first launched back in 2012. It had numerous issues with problems associated with accuracy - a huge problem for any navigation app. Nowadays though, the difference between the two is much more slight. Ultimately, whatever you use will get you to your destination via a fairly stylish and practical interface. The differences are much more subtle although you need to bear in mind that only iOS owners can use Apple Maps. It's not available in any other form, unlike Google Maps. Because of that, Google Maps has the edge for all-round convenience but it is certainly convenient that iOS device owners don't have to worry about installing a separate app. It's already ready to use on their device and updates alongside iOS. Added Siri integration is sure to help too when you're on the move. Much of which one you favor is likely to come down to personal preference. Is Google Maps better than Apple Maps? Once upon a time, it was a no brainer. Google Maps, having launched in 2005 and having plenty of time to refine its services and improve over the years, was easily better than Apple Maps. "Google Map it" soon became part of the vernacular for many people and its introduction of Street View appealed to everyone's urge to look around the world from the comfort of their home. Apple Maps didn't launch until 2012 (before that iOS devices used Google Maps as its navigational tool). Apple Maps launched with features to rival most of Google Maps' features. The early days of Apple Maps were fraught with issues but such problems have been mostly rectified in recent times thanks to iOS 13. To some, Apple Maps still feels like the new kid in class but it's a much closer competition than before. Both Apple Maps and Google Maps are quite similar in how things are laid out. As soon as you open either app, you can immediately type in the location you want to head to and the respective app does all the hard work for you. It's intuitive stuff for the most part although there are some differences. Notably, Apple Maps offers a somewhat flatter looking layout. Smaller text and icons may look good and in keeping with the iOS aesthetic, but Google Maps uses brighter and larger icons to make the interface seem a little more eye-catching. However, Apple Maps uses custom icons for key landmarks like the Golden Gate Bridge, as well as shows the current weather for such locations, making it a stylish option again. One of the biggest and most useful features is being able to gain a street-level view. Apple Maps calls it Look Around while Google calls it Street View. Both work well but Google Maps has the edge here, plus it takes into consideration bicycle routes while Apple Maps hasn't fully caught up here yet. Google Maps generally has more 3D models of many buildings and a couple of extra modes for looking at locations. When it comes to navigation, both services are quite effective, whether you're walking or driving, with appropriate and accurate turn-by-turn navigation. Google Maps offers extra information about nearby locations on the screen while you need to tap to find it on Apple Maps, but that can mean a slightly less cluttered interface than Google Maps'. Both apps offer arrival estimations based on current traffic conditions and they're both usually fairly accurate. Thanks to Google Maps being available on more devices as well as in a web interface, it's simpler to transfer addresses and locations via your Google account and syncing up, than with Apple Maps, although this does come down to how tied into the Apple ecosystem you are. Outside of basic navigational features, both Apple Maps and Google Maps offer some useful extras. The biggest one for Apple Maps is that it has Siri integration. Just speak to your iOS device and it'll tell you exactly how to get somewhere with Siri Natural Language Guidance ensuring it speaks in an understandable manner. Apple Maps also typically uses slightly less data than Google Maps which can be handy, but there's a catch here. Google Maps is the only one of the two to offer an offline mode which immediately makes data usage less of an issue. It does require some forward planning though so there are pros and cons here. Apple Maps also has a Flyover mode which lets you tour various city landmarks as well as explore densely populated areas with 3D models of key structure. It's impressive if not exactly something you'd use every day. Integration of Yelp reviews for locations is something you'll use every day though and is something that Apple Maps has instead of Google Maps. On the other hand, Google Maps has bicycle maps at a time when Apple Maps only has bike-sharing stations listed. Bicycle maps immediately make Google Maps a far superior option if you regularly cycle and could do with help with navigation. If you're privacy-conscious, it's worth paying attention to how both Apple and Google deal with your data. Via Apple Maps, it's possible to access many features without needing to sign in to an account. A lot of the information remains on your device rather than in the cloud with Apple adamant that it doesn't record a history of what you search for or the locations you visited. Instead, any data on your device is fragmented as part of its privacy protection, leaving no one other than you knowing your whole route. In contrast, Google Maps' data resides on the cloud so that you're able to easily switch between the website and the app. It has numerous customization features such as Incognito mode so that your searches and locations are kept private, however. You do need to remember to set these up though. Google has a location timeline otherwise that tracks everywhere you've been. The clear winner between Apple Maps and Google Maps, for most people, is Google Maps. That's in part because it's available on more devices. It also offers a more intuitive interface and slightly better accuracy when tracking locations. Regular cyclists will appreciate its bicycle maps too. However, Apple Maps is still very appealing if you're an iOS device owner. It has plenty of useful features like Siri integration, Flyover mode, and more secure response to privacy concerns. There was a time when Apple Maps may have struggled to keep up with Google Maps but that isn't an issue any longer. Whichever choice you make, you'll be happy with the results. It's just that Google Maps has the edge right now. That could well change in the future with Apple regularly updating Apple Maps as part of iOS. Thanks for letting us know! Tell us why! With iOS 13, Apple introduced several additional features to its Maps app, one of which is called Look Around. This gives you a street-level view of what's around your current location or the location you search for on the map. If you've ever used Google Street View, you already have a good idea of how Look Around works, but Apple's equivalent feature includes a couple of functions that differentiate it from Google Maps. Launch the Apple Maps app on your iPhone or iPad, and then check to see if there's a binoculars icon on the map in your exact location. (Tap the location arrow in the floating menu of options if another area of the map is showing that's different to where you're at). If you see a pair of binoculars on the map, simply tap them to open a street-level view in a card overlay at the top of the screen. You can also tap the two arrows pointing away from each other in the top left corner of the card to take the street-level view fullscreen. Note that you should also see the binoculars icon available to tap in the floating menu when checking the standard overhead map in a supported location. If Look Around isn't yet supported in your current location, you can still search for specific locations supported by Look Around. For example, try searching for San Francisco and you'll see a Look Around icon in the results overlay. Once you're in Look Around mode, tap the view to move through the area. You can also tap a spot further in the distance and the view will smoothly zoom towards the location. To help orient you in Look Around mode, points of interest such as bars, restaurants, parks and the like are identified by floating icons at street level. Note however that you can only zoom into areas that can be accessed by vehicles, because the Look Around data is captured by cars fitted with 360-degree cameras. Currently, Look Around in Maps is limited to areas in California, Nevada, and Hawaii, but Apple plans to expand availability in 2019 and beyond. 1 What Is 7mm in Inches? 2 What Are the Values of Holiday Barbie Dolls? 3 How Do I Find My ISP Username and Password? 4 How Much Did Things Cost in 1939? 5 Which Is Better — A Small Family Or Big Family? 1 What Is a Four-Function Calculator? 2 Which Elements Are Named After Planets? 3 Hunter S. What is the precise location of Los Angeles? It can be stated in relative terms (about 3,000 miles west of New York, for example), but for a cartographer, pilot, geologist, or geographer, a much more specific measurement is needed. In order to precisely locate any spot in the world, therefore, we use a geographic coordinate system that is measured in degrees of latitude and longitude. This system starts with an imaginary grid of lines that cover the entire planet. Locations are measured based on both X and Y coordinates within the grid. Because the Earth is round, however, the distances between lines on the grid vary. Longitude is defined as imaginary lines called meridians that run from the north to the south pole. There are a total of 360 meridians. The Prime Meridian runs through the Greenwich Observatory in England, the location agreed upon by a conference in 1884 to be 0 degrees. On the opposite side of the Earth is the international date line at approximately 180 degrees longitude, though the date line does not follow an exact straight line. (This keeps countries from being in different days.) When a person crosses the international date line traveling from west to east, they move up one day. They move back one day when traveling east to west. Latitude is defined as imaginary lines called parallels because they are parallel to the equator and to one another. The equator, which runs in a circle around the center of the Earth, divides the planet into north and south hemispheres. Lines of latitude and longitude intersect, creating a grid that allows anyone in any location to pinpoint a geographic location. There are 360 degrees of longitude (because meridians make Great Circles around the globe), and there are 180 degrees of latitude. To further specify exactly where to find anything on Earth, measurements are stated not only in degrees but also in minutes and seconds. Each degree can be broken into 60 minutes, and each minute can be divided into 60 seconds. Any given location can be described in terms of degrees, minutes, and seconds of longitude and latitude. Degrees of latitude are parallel so, for the most part, the distance between each degree remains constant. However, the Earth is slightly elliptical in shape and that creates a small variation between the degrees as we work our way from the equator to the north and south poles. Each degree of latitude is approximately 69 miles (111 kilometers) apart. At the equator, the distance is 68.703 miles (110.567 kilometers). At the Tropic of Cancer and Tropic of Capricorn (23.5 degrees north and south), the distance is 68.94 miles (110.948 kilometers). At each of the poles, the distance is 69.407 miles (111.699 kilometers). This is rather convenient when you want to know how far it is between each degree, no matter where you are on Earth. All you need to know is that each minute (1/60th of a degree) is approximately one mile. For example, if we were at 40 degrees north, 100 degrees west, we would be on the Nebraska-Kansas border. If we were to go directly north to 41 degrees north, 100 degrees west, we would have traveled about 69 miles and would now be near Interstate 80. Unlike latitude, the distance between degrees of longitude varies greatly depending upon your location on the planet. They are farthest apart at the equator and converge at the poles. A degree of longitude is widest at the equator with a distance of 69.172 miles (111.321 kilometers). The distance gradually shrinks to zero as they meet at the poles. At 40 degrees north or south, the distance between a degree of longitude is 53 miles (85 kilometers). The line at 40 degrees north runs through the middle of the United States and China, as well as Turkey and Spain. Meanwhile, 40 degrees south is south of Africa, goes through the southern part of Chile and Argentina, and runs almost directly through the center of New Zealand. What if you are given two coordinates for latitude and longitude and you need to know how far it is between the two locations? You could use what is known as a haversine formula to calculate the distance — but unless you are a whiz at trigonometry, it is not easy. Luckily, in today's digital world, computers can do the math for us. Most interactive map applications will allow you to input GPS coordinates of latitude and longitude and tell you the distance between the two points. There are a number of latitude/longitude distance calculators available online. The National Hurricane Center has one that is very easy to use. Keep in mind that you can also find the precise latitude and longitude of a location using a map application. In Google Maps, for example, you can simply click on a location and a pop-up window will give latitude and longitude data to a millionth of a degree. Similarly, if you right-click on a location in MapQuest you will get the latitude and longitude data. "Latitude/Longitude Distance Calculator." National Hurricane Center and Central Pacific Hurricane Center.
